Psoriasis is a chronic autoimmune skin condition that affects ≈8 million Americans [1]. Approximately 10% of affected Americans have moderate-to-severe psoriasis that necessitates use of phototherapy or systemic medications, yet many patients remain undertreated [2,3]. According to a survey undertaken by the National Psoriasis Foundation in 2001, 40% of respondents felt frustrated with the ineffectiveness of therapies, and 32% felt that treatment was not sufficiently aggressive [4].

Biologic medications (“biologics”) have revolutionized the management of psoriasis but at a higher cost compared with “traditional” agents. Cost must be considered when evaluating management options for psoriasis.

Objective: To estimate the annual cost of treatment of psoriasis using biologic agents and assess the trend over the past decade.

Methods: The cost of annual treatment paradigms for etanercept, adalimumab, and ustekinumab was estimated using the average wholesale price. Trends were assessed by calculating the percentage change in annual cost compared with the previous year. A sales-based cost of drugs was estimated using gross US sales of each drug and an estimate of the total number of patients treated based on prescription data.

Results: The cost of one year of induction and maintenance treatment was highest for ustekinumab ($53,909), followed by etanercept ($46,395), and adalimumab ($39,041). The sales-based cost of drugs was greatest for ustekinumab ($25,012), then adalimumab ($6,786) and etanercept ($6,629). Sales-based cost increased at an average of 20% per year.

Conclusion: The cost of biologic treatments for psoriasis has been increasing. Cost considerations in the management of psoriasis are likely to increase given the limited healthcare resources that are available.

Keywords: cost analysis, etanercept, adalimumab, ustekinumab, psoriasis

Introduction

Psoriasis Area and Severity Index (PASI) outcomes; and increased satisfaction by patients [7,8].

There are two main categories of biologic treatments for psoriasis: tumor necrosis factor (TNF)-α inhibitors (e.g. etanercept, adalimumab) and interleukin-12/23 inhibitors (e.g. ustekinumab). Cost analyses of these drugs have yielded estimates from $7,993 a year to $48,000 a year [9–11]. Given these high sums, cost is an important consideration for physicians and patients before choosing a biologic agent.

Here, we provide an updated estimate of the annual cost of etanercept, adalimumab, and ustekinumab, and review the literature regarding cost analyses pertinent to these drugs. We also discuss the growing role of cost-effectiveness in treatment guidelines.

Methods

Annual drug costs

Annual drug costs were estimated for etanercept, adalimumab, and ustekinumab. The cost of each drug was estimated...
according to the average wholesale price (AWP) from the *Red Book Drug Topics*, 2014 [12]. All costs were calculated in US dollars. Additional costs, such as hospitalizations, physician visits, laboratory tests, and adverse events, were not included in this cost analysis. The cost of etanercept was based on a recommended initiation treatment regimen of 50 mg twice weekly for 3 months, followed by 50 mg once weekly [13]. For adalimumab, the cost estimate consisted of an 80-mg loading dose, followed by 40 mg every other week beginning one week after the initial dose [14]. For ustekinumab, recommended treatment doses differ depending on patient weight (≤100 kg or >100 kg). Consequently, a patient weight of 80 kg was assumed. The annual cost estimate included a dose of 45 mg at 0- and 4-weeks, and 45 mg every 12 weeks thereafter [15].

A trend of drug costs from 2004 to 2014 was calculated using the AWP/unit specific to each year listed in *Red Book Drug Topics* for each drug. Annual cost was then estimated using the same treatment paradigm as outlined above. In addition, the percentage change in annual cost was calculated, and compared with overall annual inflation and annual healthcare inflation.

**Estimation of “sales-based cost”**

Wholesale prices may not provide an accurate measure of what payers are paying for biologics because prices may be modified by contract issues. To estimate cost after accounting for drug discounting, a sales-based estimate of cost for a biologic drug for psoriasis was calculated using the following formula:

\[
\text{Sales-based cost of drugs} = \frac{\text{gross US sales (})}{\text{total number of patients treated}}
\]

Gross sales in the US were appraised through the 2013 Securities and Exchange Commission 10K Annual Reports for Amgen and Abbvie, the producers of etanercept and adalimumab, respectively [16,17]. Sales of ustekinumab were monitored through annual sales and earnings reports for Johnson and Johnson [18].

A direct estimate of the total number of patients taking each drug was not available. To estimate the total number of patients taking each drug, we used prescription data available on the Bloomberg L.P. database to determine the total number of prescriptions (refills and new) from 2011 to 2013. The total number of prescriptions (refills and new) each year was divided by two based on the assumption that each psoriasis patient receives two prescriptions a year for biologic agents. Information from the database is derived from Symphony Health Solutions (provider of data on prescription audits in the US). It provides information on weekly and monthly retail, non-retail, and mail-order prescription activity.

**Results**

**Expected annual costs for biologic drugs**

Estimated annual cost of biologic treatment ranged from $36,038 (adalimumab) to $44,924 (ustekinumab). The cost was higher during the first year (when loading doses are required): $46,395 vs $37,111 for etanercept, $39,041 vs $36,038 for adalimumab, and $53,909 vs $44,924 for ustekinumab (Table 1).

All three drugs increased in cost from 2004 to 2014 (Figure 1). The percentage change in cost for etanercept from 2004 to 2014 was 120%, for adalimumab from 2004 to 2013 was 103%, and for ustekinumab from 2010 to 2014 was 53%. For the five-year interval 2010–2014, the change in cost for etanercept was 48% and for adalimumab was 64%.

The average annual rate of increase was of the same order of magnitude for all three drugs: 8.2% for etanercept, 9.2% for adalimumab, and 11.0% for ustekinumab (Figure 2).

aDosing regimens for adalimumab and ustekinumab are based on FDA recommendations. Dosing regimen for etanercept is based on the PRESTA trial [13].

bAverage wholesale price was determined from the *Red Book Drug Topics*, 2014 [12].
These rates of increase were higher than the overall inflation rate of 1.5% and the overall healthcare inflation rate of 2.5% [19,20].

**Sales-based cost of drugs**

Our sales-based cost of drugs was lower than published wholesale cost rates, which may reflect the effects of contracting (as was anticipated; Table 2). Sales-based cost in 2013 was greatest for ustekinumab ($25,012), followed by adalimumab and etanercept, which were priced similarly at $6,786 and $6,629, respectively (Table 2). The percent change in price from 2011 to 2013 was 17–23% for etanercept and adalimumab, and 11–39% for ustekinumab.
Compared with biologic treatment of other systemic immune-mediated diseases, the cost of biologic therapy for psoriasis is similar or slightly lower. For example, certolizumab pegol for rheumatoid arthritis costs $79,750 a year based on the AWP at a maintenance regimen of 200 mg every other week [12]. Natalizumab is used in a regimen for Crohn’s disease of 300 mg every 4 weeks, and costs $67,370 a year based on wholesale prices [12].

Balancing efficacy and cost in guidelines

Given the economic climate, it is prudent to consider cost-effectiveness when establishing treatment guidelines. The UK National Institute for Health and Clinical Excellence (NICE) incorporates efficacy and cost-effectiveness in the recommendations in its guidelines [29]. These guidelines suggest that methotrexate should be the first agent used in individuals who meet the criteria for systemic therapy. There is no recommendation as to which biologic agent should be administered first. However, the guidelines recommend use of biologics including ustekinumab, etanercept, or adalimumab if the psoriasis is severe (PASI ≥10 and Dermatology Life Quality Index (DLQI) > 10) and has not responded to systemic therapies including cyclosporine, methotrexate, and psoralen combined with ultraviolet A, or if the patient has a contraindication to these therapies (e.g. pregnancy, leukopenia) [29,30].

Treatment guidelines set by the British Association of Dermatology in 2009 recommend use of TNF-α inhibitors before ustekinumab because there had been limited exposure by patients to ustekinumab at the time the guidelines were established.

**Discussion**

The cost of one year of induction and maintenance treatment was highest for ustekinumab ($53,909), followed by etanercept ($46,395), and adalimumab ($39,041). These estimates are considerably higher compared with previous estimates: $7,993 to $48,731 per year for etanercept, $19,000 to $37,000 for adalimumab, and $15,243 to $34,951 for ustekinumab [1,9–11,21–24]. These differences may be attributable to: differences in treatment paradigms; variations in valuation methodology; increases in the AWP of drugs over time. For example, some studies included the cost of laboratory tests and office visits [1,9,10,21,23], and used the wholesale acquisition price for drug costs [25,26]. The AWP is typically set 20–25% above the wholesale acquisition cost or list price [27]. These studies were conducted several years ago and our calculations suggest that the AWP increased over time, especially for ustekinumab (>50% over five years). Hence, it is likely that our higher estimate is also due to a rising AWP.

Inflation could be another potential cause for the higher costs estimated in this analysis. However, our calculated increases in cost clearly outstrip the increase in Consumer Price Index-Urban for overall and healthcare-specific inflation – a finding that echoes the work of Beyer et al. [22]. Other factors that may be responsible (at least in part) for rising costs include: increasing costs for research and development; costs of subject recruitment; increasing competition in the market for drugs with similar efficacies; increasing safety regulation (which translates into longer and more complicated clinical trials) [28]. Biologic agents are also more complicated to produce compared with more “traditional” therapies [22].
were written. However, since then, favorable five-year safety data have been reported [31]. In contrast, treatment guidelines from the American Academy of Dermatology in 2011 for moderate-to-severe psoriasis do not specify the sequence by which biologics should be prescribed.

A review of cost-effectiveness studies on biologic agents in psoriasis yielded inconsistent results for the most cost-effective agent (Supplemental Table 1), probably because different patient cohorts and agents were studied [9–11,21,23,25,26,32–35]. Conclusions drawn from

Supplemental Table 1. Summary of cost-effectiveness analyses of biologic agents for psoriasis based on US pricing.

aStudy included non-biologic agents (i.e. phototherapy, cyclosporine, methotrexate, acitretin).

RCT, randomized controlled trial; PASI, Psoriasis Area and Severity Index; DLQI MID, Dermatology Life Quality Index Minimally Important Difference; PGA 0/1, Physician Global Assessment clear/minimal; ACCEPT, Active Comparator (CNTO1275/Enbrel) Psoriasis Trial; AWP, average wholesale price; WAC, wholesale acquisition cost.
cost-effectiveness models should be interpreted with caution because they rely on data drawn from idealized conditions for randomized controlled trials, a study period of 12 weeks, and drug prices that may not reflect the contracted price of the drug paid by insurers.

Our cost analysis had several limitations. First, other direct costs, such as physician visits, laboratory tests, and treatment for adverse events, were not included. However, they are likely to have been minimal compared with the cost of biologic drugs. Indirect costs (including comorbidities and increased mortality with severe psoriasis) are also important considerations. However, we could not measure these costs, so they were not included in this therapeutics-specific analysis.

Second, in our estimate of the sales-based cost according to the total number of patients treated with biologic drugs, we assumed that patients fill two prescriptions each year, but this “ballpark estimate” may not reflect true prescribing patterns. Lastly, our estimate of sales-based cost does not reflect the specific contracts and prices of the insurers of individual patients. Thus, if choosing a therapy for a specific patient, then estimates of which drug is the most expensive may not apply because we do not know that contracted drug-purchasing rates of the insurer. We did not have access to insurance databases in this study, but using data from these sources may be helpful in future studies.

Psoriasis is a chronic, long-term condition, so awareness of treatment costs is important. Our cost analysis demonstrates that the annual cost of drugs is expensive and continues to increase each year. New oral therapies on the market may provide less costly alternatives. For example, apremilast, an inhibitor of phosphodiesterase-4 approved by the Food and Drug Administration in March 2014 for psoriatic arthritis, costs $27,375 a year based on wholesale pricing of a dose of 30 mg twice a day. However, with a lower efficacy rate, it may not be more cost-effective [10]. Tofacitinib, an inhibitor of JAK-kinase – if used for psoriasis at 5 mg twice a day – would cost $32,000 a year based on wholesale prices [12]. It is hoped that “biosimilars” will lower the cost of biologic agents. However, biosimilars are anticipated to cost only 20–30% less than branded biologics – a less drastic reduction in cost compared to generics which, at least in the past, lowered prices ≤90% [36]. As a significantly low-cost, highly effective, safe alternative to biologics for patients who have failed conventional therapy is not on the horizon, costs will continue to play a part in the choice of therapy for severe psoriasis.
